The present invention pertains to the art of power electronics, and more particularly, to power supply distribution systems. The use of power electronics to regulate/convert power is known in the art. A simple example of such power electronics includes a power switching switch and a control circuit to control the on/off state of the switch. Another example of such power electronics includes a power regulating switch (e.g., one or more power semiconductors) to convert power from a high to a low voltage and associated control circuits to control the power regulating switch. However, typical power distribution systems used to convert power utilize large, multi-phase wiring configurations to deliver and receive power. This results in a complex, costly system, and has a negative impact on manufacturing costs. In one aspect of the present invention, an arrangement for distributing power includes a housing including a first opening to permit power to flow to the housing, and a second opening to permit power to exit the housing. A wire harness assembly is located within the housing for supplying and receiving power. The wire harness assembly includes a first insulator and a second insulator. A first conductor is connected to the first insulator and to the first opening of the housing. A second conductor is connected to the second insulator and to the second opening of the housing. The first and second conductors are connected to each other at a first connector portion and at a second connector portion. The first and second connectors are rotatably mounted to each other, and rotatably mounted to the housing. In another aspect of the present invention, an arrangement for distributing power includes a housing including a first opening to permit power to flow to the housing, and a second opening to permit power to exit the housing.
